ACAN2517FD Arduino library
For `MCP2517FD`, in CAN FD mode
Version 1.1.6

Pierre Molinaro

June 6, 2019

Contents

1 Versions

Version	Date	Comment
1.1.6	June 6, 2019	Running `pinMode (mINT, INPUT_PULLUP)` only if `mInt` pin is used (thanks to `Tyler Lewis`).
1.1.5	June 2, 2019	Fixed a race condition on ESP32 (thanks to `Nick Kirkby`).
1.1.4	March 21, 2019	Fixed dual bit rate bug (thanks to danielhenz).
		Fixed TxQ enable bug (thanks to danielhenz).
		Added setting of *Enable Edge Filtering during Bus Integration state bit*, for reaching the 8 Mbit/s bit data rate.
		Updated `LoopBackIntensiveTestTeensy3x` sample code.
1.1.3	February 8, 2019	Compatibility for Arduino Uno.
		Added demo sketch `LoopBackDemoArduinoUno`.
		Renamed `ACANBuffer` to `ACANFDBuffer`.
1.1.2	February 3, 2019	Added setting `mINTIsOpenDrain` (section 19.11.2 page 40).
		Remove useless mutex (ESP32).
1.1.1	January 31, 2019	First release running on ESP32 (section 7.4 page 13).
		New option: no interrupt pin (section 7.5 page 15).
1.0.4	January 14, 2019	Fixed mask and acceptance filters for extended messages.
		New `LoopBackDemoTeensy3xStandardFilterTest.ino` sample code for checking standard reception filters.
		New `LoopBackDemoTeensy3xExtendedFilterTest.ino` sample code for checking extended reception filters.
1.0.3	January 6, 2019	Corrected identifiers for extended messages.
1.0.2	November 2, 2018	added `mISOCRCEnabled` setting
1.0.1	October 29, 2018	Conformity with Arduino library
1.0.0	October 28, 2018	Initial release

2 Features

The `ACAN2517FD` library is a MCP2517FD CAN ("Controller Area Network") Controller driver for any board running Arduino. It handles CAN FD frames.

This library is compatible with:

- the ACAN 1.0.6 and above library (https://github.com/pierremolinaro/acan), CAN driver for FlexCan module embedded in Teensy 3.1 / 3.2, 3.5, 3.6 microcontrollers;

- the ACAN2515 1.0.1 and above library (https://github.com/pierremolinaro/acan2515), CAN driver for `MCP2515` CAN controller;

- the ACAN2517 library (https://github.com/pierremolinaro/acan2517), CAN driver for `MCP2517FD` CAN controller, in CAN 2.0B mode.

It has been designed to make it easy to start and to be easily configurable:

- default configuration sends and receives any frame – no default filter to provide;

- ISO CRC enabled by default;

- efficient built-in CAN bit settings computation from arbitration and data bit rates;

- user can fully define its own CAN bit setting values;

- all 32 reception filter registers are easily defined;

- reception filters accept call back functions;

- driver and controller transmit buffer sizes are customisable;

- driver and controller receive buffer size is customisable;

- overflow of the driver receive buffer is detectable;

- `MCP2517FD` internal RAM allocation is customizable and the driver checks no overflow occurs;

- *loop back*, *self reception*, *listing only* MCP2517FD controller modes are selectable.

3 Data flow

Two figures illustrate message flow for sending and receiving CAN FD messages: figure 1 is the default configuration, figure 2 is the customized configuration.

3.1 Data flow in default configuration

The figure 1 illustrates message flow in the default configuration.

Sending messages. The ACAN2517FD driver defines a *driver transmit FIFO* (default size: 16 messages), and configures the `MCP2517FD` with a *controller transmit FIFO* with a size of 4 messages. `MCP2517FD` RAM has a capacicity of 2048 bytes, that limits the sizes of the *controller transmit FIFO* and *controller receive FIFO*. See section 13 page 20.

A message is defined by an instance of `CANFDMessage` class. For sending a message, user code calls the `tryToSend` method – see section 14 page 21, and the `idx` property of the sent message should be equal to 0 (default value).

Figure 1 – Message flow in `ACAN2517FD` driver and `MCP2517FD` CAN Controller, default configuration

Receiving messages. The MCP2517FD *CAN Protocol Engine* transmits all correct frames to the *reception filters.* By default, they are configured as pass-all, see section 16 page 24 for configuring them. Messages that pass the filters are stored in the *Controller Reception FIFO*; its size is 24 message by default. The interrupt service routine transfers the messages from this FIFO to the *Driver Receive FIFO.* The size of the *Driver Receive Buffer* is 32 by default – see section 15.1 page 23 for changing the default value. Three user methods are available:

- the `available` method returns `false` if the *Driver Receive Buffer* is empty, and `true` otherwise;

- the `receive` method retrieves messages from the *Driver Receive Buffer* – see section 15 page 22;

- the `dispatchReceivedMessage` method if you have defined the reception filters that name a call-back function – see section 17 page 27.

3.2 Data flow, custom configuration

The figure 2 illustrates message flow in a custom configuration.

Note. The *transmit Event FIFO* and the `transmitEvent` function are not currently implemented.

You can allocate the *Controller transmit Queue*: send order is defined by frame priority (see section 10 page 18). You can also define up to 32 receive filters (see section 16 page 24). Sizes of `MCP2517FD` internal buffer are easily customizable.
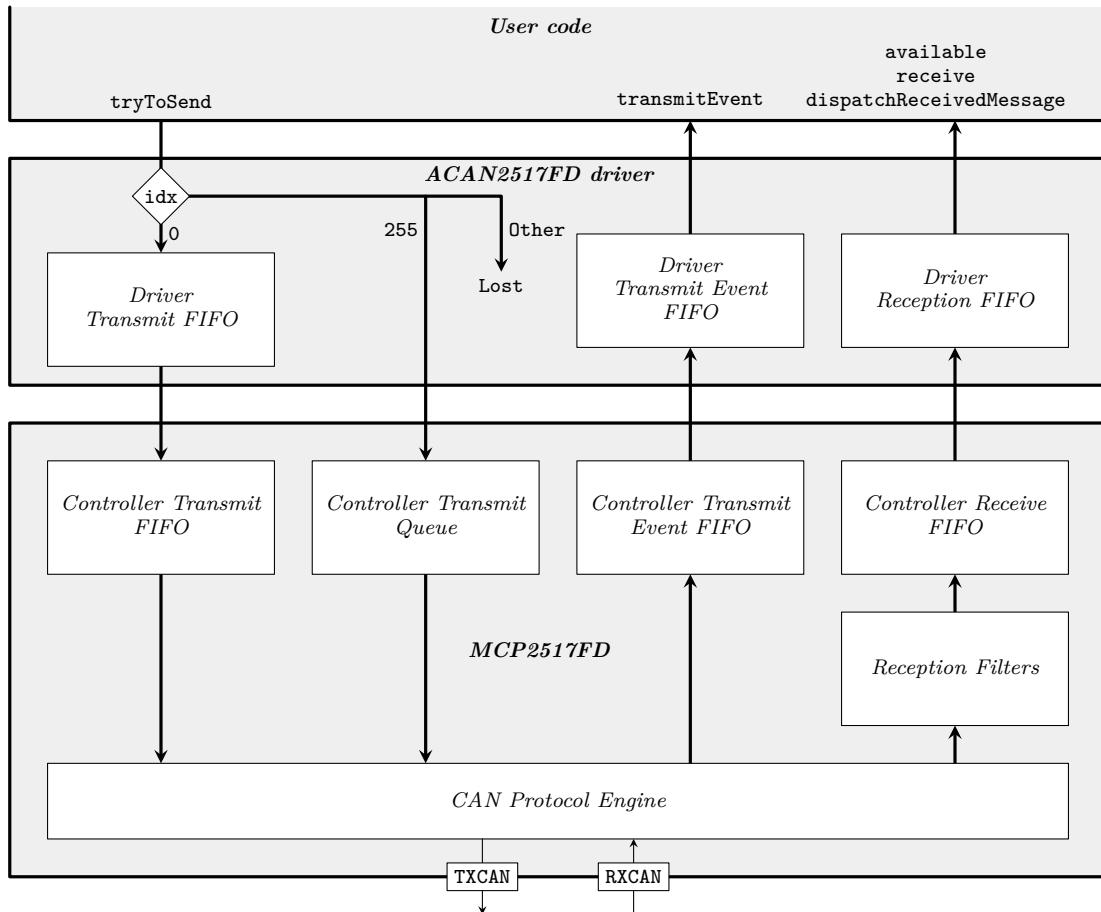

Figure 2 – Message flow in `ACAN2517FD` driver and `MCP2517FD` CAN Controller, custom configuration

4 A simple example: `LoopBackDemo`

The following code is a sample code for introducing the `ACAN2517FD` library, extracted from the `LoopBackDemo` sample code included in the library distribution. It runs natively on any Arduino compatible board, and is easily adaptable to any microcontroller supporting `SPI`. It demonstrates how to configure the driver, to send a CAN message, and to receive a CAN message.

Note: this code runs without any CAN transceiver (the `TXCAN` and `RXCAN` pins of the `MCP2517FD` are left open), the `MCP2517FD` is configured in the *loop back* mode.

```
#include <ACAN2517FD.h>
```

This line includes the `ACAN2517FD` library.

```
static const byte MCP2517_CS  = 20 ; // CS input of MCP2517FD
static const byte MCP2517_INT = 37 ; // INT output of MCP2517FD
```

Define the pins connected to $\overline{\text{CS}}$ and $\overline{\text{INT}}$ pins (adapt to your design).

```
ACAN2517FD can (MCP2517_CS, SPI, MCP2517_INT) ;
```

Instanciation of the `ACAN2517FD` library, declaration and initialization of the `can` object that implements the driver. The constructor names: the number of the pin connected to the $\overline{\text{CS}}$ pin, the `SPI` object (you can use `SPI1`, `SPI2`, …), the number of the pin connected to the $\overline{\text{INT}}$ pin.

```
void setup () {
//--- Switch on builtin led
  pinMode (LED_BUILTIN, OUTPUT) ;
  digitalWrite (LED_BUILTIN, HIGH) ;
//--- Start serial
  Serial.begin (38400) ;
//--- Wait for serial (blink led at 10 Hz during waiting)
  while (!Serial) {
    delay (50) ;
    digitalWrite (LED_BUILTIN, !digitalRead (LED_BUILTIN)) ;
  }
```

Builtin led is used for signaling. It blinks led at 10 Hz during until serial monitor is ready.

```
  SPI.begin () ;
```

You should call `SPI.begin`. Many platforms define alternate pins for SPI. On Teensy 3.x (section 7.2 page 11), selecting alternate pins should be done before calling `SPI.begin`, on Adafruit Feather M0 (section 7.3 page 12), this should be done after. Calling `SPI.begin` explicitly allows you to fully handle alternate pins.

```
  ACAN2517FDSettings settings (ACAN2517FDSettings::OSC_4MHz10xPLL,
                               125 * 1000, ACAN2517FDSettings::DATA_BITRATE_x4) ;
```

Configuration is a four-step operation. This line is the first step. It instanciates the `settings` object of the `ACAN2517FDSettings` class. The constructor has three parameters: the `MCP2517FD` oscillator specification, the desired CAN arbitration bit rate (here, 125 kb/s), and the data bit rate, given by a multiplicative factor of the arbitration bit rate; here, the data bit rate is 125 kb/s * 4 = 500 kbit/s. It returns a `settings` object fully initialized with CAN bit settings for the desired arbitration and data bit rates, and default values for other configuration properties.

```
  settings.mRequestedMode = ACAN2517FDSettings::InternalLoopBack ;
```

This is the second step. You can override the values of the properties of `settings` object. Here, the `mRequestedMode` property is set to `InternalLoopBack` – its value is `NormalFD` by default. Setting this property enables *loop back*, that is you can run this demo sketch even it you have no connection to a physical CAN network. The section 19.11 page 39 lists all properties you can override.

```
  const uint32_t errorCode = can.begin (settings, [] { can.isr () ; }) ;
```

This is the third step, configuration of the `can` driver with `settings` values. The driver is configured for being able to send any (standard / extended, data / remote) frame, and to receive all (standard / extended, data / remote) frames. If you want to define reception filters, see section 16 page 24. The second argument is the *interrupt service routine*, and is defined by a C++ lambda expression[1]. See section 18.2 page 28 for using a function instead.

```
  if (errorCode != 0) {
    Serial.print ("Configuration error 0x") ;
    Serial.println (errorCode, HEX) ;
  }
}
```

Last step: the configuration of the `can` driver returns an error code, stored in the `errorCode` constant. It has the value 0 if all is ok – see section 18.3 page 28.

```
static uint32_t gBlinkLedDate = 0 ;
static uint32_t gReceivedFrameCount = 0 ;
static uint32_t gSentFrameCount = 0 ;
```

[1]https://en.cppreference.com/w/cpp/language/lambda

The `gSendDate` global variable is used for sending a CAN message every 2 s. The `gSentCount` global variable counts the number of sent messages. The `gReceivedCount` global variable counts the number of received messages.

```
void loop() {
  CANFDMessage frame ;
```

The `message` object is fully initialized by the default constructor, it represents a standard data frame, with an identifier equal to 0, and without any data – see section 5 page 8.

```
if (gBlinkLedDate < millis ()) {
  gBlinkLedDate += 2000 ;
  digitalWrite (LED_BUILTIN, !digitalRead (LED_BUILTIN)) ;
  const bool ok = can.tryToSend (frame) ;
  if (ok) {
    gSentFrameCount += 1 ;
    Serial.print ("Sent: ") ;
    Serial.println (gSentFrameCount) ;
  }else{
    Serial.println ("Send failure") ;
  }
}
```

We try to send the data message. Actually, we try to transfer it into the *Driver transmit buffer*. The transfer succeeds if the buffer is not full. The `tryToSend` method returns `false` if the buffer is full, and `true` otherwise. Note the returned value only tells if the transfer into the *Driver transmit buffer* is successful or not: we have no way to know if the frame is actually sent on the the CAN network. Then, we act the successfull transfer by setting `gSendDate` to the next send date and incrementing the `gSentCount` variable. Note if the transfer did fail, the send date is not changed, so the `tryToSend` method will be called on the execution of the `loop` function.

```
  if (can.available ()) {
    can.receive (frame) ;
    gReceivedFrameCount ++ ;
    Serial.print ("Received: ") ;
    Serial.println (gReceivedFrameCount) ;
  }
}
```

As the `MCP2517FD` controller is configured in *loop back* mode, all sent messages are received. The `receive` method returns `false` if no message is available from the *driver reception buffer*. It returns `true` if a message has been successfully removed from the *driver reception buffer*. This message is assigned to the `message` object. If a message has been received, the `gReceivedCount` is incremented ans displayed.

5 The `CANFDMessage` class

Note. The `CANFDMessage` class is declared in the `CANFDMessage.h` header file. The class declaration is protected by an include guard that causes the macro `GENERIC_CANFD_MESSAGE_DEFINED` to be defined. This allows an other library to freely include this file without any declaration conflict.

A CAN FD message is an object that contains all CAN FD frame user informations. All properties are initialized by default, and represent a standard data frame, with an identifier equal to 0, and without any data.

```
class CANFDMessage {
  public : uint32_t id = 0 ;   // Frame identifier
  public : bool ext = false ; // false -> standard frame, true -> extended frame
  public : bool rtr = false ; // false -> data frame, true -> remote frame
  public : uint8_t idx = 0 ;   // Used by the driver
```

```
  public : uint8_t len = 0 ;   // Length of data (0 ... 64)
  public : union {
    uint64_t data64 [ 8] ; // Caution: subject to endianness
    uint32_t data32 [16] ; // Caution: subject to endianness
    uint16_t data16 [32] ; // Caution: subject to endianness
    uint8_t  data   [64] = {} ;
  } ;
  ...
} ;
```

Note the message datas are defined by an **union**. So message datas can be seen as 64 bytes, 32 x 16-bit unsigned integers, 16 x 32-bit, or 8 x 64-bit. Be aware that multi-byte integers are subject to endianness (Cortex M4 processors of Teensy 3.x are little-endian).

Example: The `message` object describes an extended frame, with identifier equal to `0x123`, that contains 12 bytes of data:

```
CANFDMessage message ; // message is fully initialized with default values
message.id = 0x123 ; // Set the message identifier (it is 0 by default)
message.ext = true ;  // message is an extended one (it is a standard one by default)
message.len = 12 ; // message contains 12 bytes (0 by default)
message.data [0] = 0x12 ; // First data byte is 0x12
...
message.data [11] = 0xCD ; // 11th data byte is 0xCD
```

5.1   The `len` property

Note that `len` field contains the actual length, not its encoding in CAN FD frames. So valid values are: 0, 1, ..., 8, 12, 16, 20, 24, 32, 48, 64. Having other values is an error that prevents frame to be sent by the `ACAN2517FD::tryToSend` method. You can use the `pad` method (see below) for padding with `0x00` bytes to the next valid length

5.2   The `idx` property

The `idx` property is not used in CAN FD frames, but:

- for a received message, it contains the acceptance filter index (see);

- on sending messages, it is used for selecting the transmit buffer (see).

5.3   The `pad` method

```
void CANFDMessage::pad (void) ;
```

The `CANFDMessage::pad` method appends zero bytes to datas for reaching the next valid length. Valid lengths are: 0, 1, ..., 8, 12, 16, 20, 24, 32, 48, 64. If the length is already valid, no padding is performed. For example:

```
CANFDMessage frame ;
frame.length = 21 ; // Not a valid value for sending
frame.pad () ;
// frame.length is 24, frame.data [21] is 0, frame.data [22] is 0, frame.data [23] is 0
```

5.4 The `isValid` method

```
bool CANFDMessage::isValid (void) const ;
```

Not all settings of `CANFDMessage` instances represent a valid frame. For example, there is no CAN FD remote frame, so a remote frame should have its length lower than or equal to 8. There is no constraint on extended / standard identifier (`ext` property). The table 1 page 10 lists the constraints on `rtr` and `len` properties. An `CANFDMessage` instance that checks theses conditions is valid.

Frame	rtr	len
CAN 2.0B Remote Frame	`true`	$0 \leqslant len \leqslant 8$
CAN 2.0B Data Frame	`false`	$0 \leqslant len \leqslant 8$
CAN FD Data Frame	`false`	12, 16, 20, 24, 32, 48, 64

Table 1 – `CANFDMessage` validity constraints

6 The `CANMessage` class

Note. The `CANMessage` class is declared in the `CANMessage.h` header file. The class declaration is protected by an include guard that causes the macro `GENERIC_CAN_MESSAGE_DEFINED` to be defined. The ACAN[2] (version 1.0.3 and above) driver, the ACAN2515[3] driver and the ACAN2517[4] driver contain an identical `CANMessage.h` file header, enabling using ACAN driver, ACAN2515 driver, ACAN2517 driver and ACAN2517FD driver in a same sketch.

A *CAN message* is an object that contains all CAN 2.0B frame user informations. All properties are initialized by default, and represent a standard data frame, with an identifier equal to 0, and without any data. In the `ACAN2517FD` library, the `CANMessage` class is only used for sending CAN 2.0B messages by a `ACAN2517FD::tryToSend` method.

```
class CANMessage {
  public : uint32_t id = 0 ;   // Frame identifier
  public : bool ext = false ; // false -> standard frame , true -> extended frame
  public : bool rtr = false ; // false -> data frame , true -> remote frame
  public : uint8_t idx = 0 ;   // Used by the driver
  public : uint8_t len = 0 ;   // Length of data (0 ... 8)
  public : union {
    uint64_t data64     ; // Caution: subject to endianness
    uint32_t data32 [2] ; // Caution: subject to endianness
    uint16_t data16 [4] ; // Caution: subject to endianness
    uint8_t  data   [8] = {0, 0, 0, 0, 0, 0, 0, 0} ;
  } ;
} ;
```

Note the message datas are defined by an `union`. So message datas can be seen as height bytes, four 16-bit unsigned integers, two 32-bit, or one 64-bit. Be aware that multi-byte integers are subject to endianness (Cortex M4 processors of Teensy 3.x are little-endian).

The `idx` property is not used in CAN frames, but:

- for a received message, it contains the acceptance filter index (see section 17 page 27);

---

[2] The ACAN driver is a CAN driver for FlexCAN modules integrated in the Teensy 3.x microcontrollers, https://github.com/pierremolinaro/acan.

[3] The ACAN2515 driver is a CAN driver for the `MCP2515` CAN controller, https://github.com/pierremolinaro/acan2515.

[4] The ACAN2517 driver is a CAN driver for the `MCP2517FD` CAN controller in CAN 2.0B mode, https://github.com/pierremolinaro/acan2517.

- on sending messages, it is used for selecting the transmit buffer (see section 14 page 21).

7   Connecting a `MCP2517FD` to your microcontroller

Connecting a `MCP2517FD` requires 5 pins (figure 3):

- hardware SPI requires you use dedicaced pins of your microcontroller. You can use alternate pins (see below), and if your microcontroller supports several hardware SPIs, you can select any of them;

- connecting the $\overline{\text{CS}}$ signal requires one digital pin, that the driver configures as an `OUTPUT` ;

- connecting the $\overline{\text{INT}}$ signal requires one other digital pin, that the driver configures as an external interrupt input; so this pin should have interrupt capability (checked by the `begin` method of the driver object);

- the $\overline{\text{INT0}}$ and $\overline{\text{INT1}}$ signals are not used by driver and are left not connected.
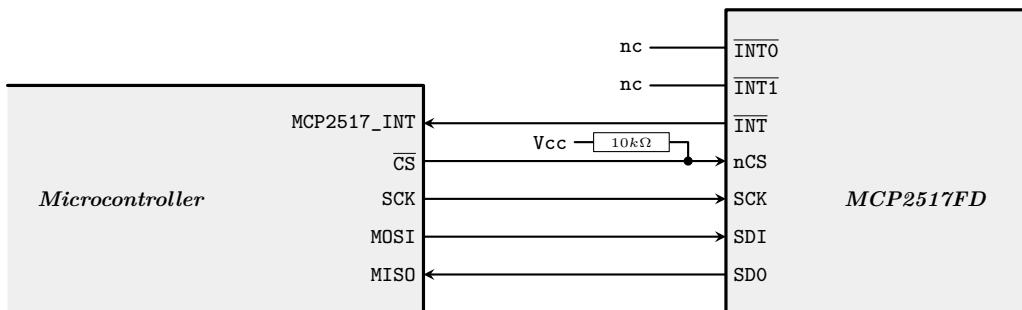

Figure 3 – `MCP2517FD` connection to a microcontroller

7.1   Pullup resistor on `nCS` pin

Note the 10 $k\Omega$ resistor between `nCS` and `Vcc`. I have experienced that this resistor is useful in the following case: a sketch using the `MCP2517FD` is running, and I upload a new sketch. During this process, the microcontroller is reset, leaving its $\overline{\text{CS}}$ pin floating. Without the 10 $k\Omega$ resistor, the `nCS` level is unpredictable, and if it becomes low, initiates transactions. I think this can crash the `MCP2517FD` firmware, and the following reset command sent by the driver not handled. With the resistor, the `nCS` level remains high until the driver sets the `nCS` as output.

7.2   Using alternate pins on Teensy 3.x

Demo sketch: `LoopBackDemoTeensy3x`.

On Teensy 3.x, ”*the main SPI pins are enabled by default. SPI pins can be moved to their alternate position with* `SPI.setMOSI(pin)`, `SPI.setMISO(pin)`, *and* `SPI.setSCK(pin)`. *You can move all of them, or just the ones that conflict, as you prefer.*”[5]

For example, the `LoopBackDemoTeensy3x` sketch uses `SPI1` on a Teensy 3.5 with these alternate pins[6]:

You call the `SPI1.setMOSI`, `SPI1.setMISO`, and `SPI1.setSCK` functions **before** calling the `begin` function of your `ACAN2517FD` instance:

---

[5]See https://www.pjrc.com/teensy/td_libs_SPI.html
[6]See https://www.pjrc.com/teensy/pinout.html
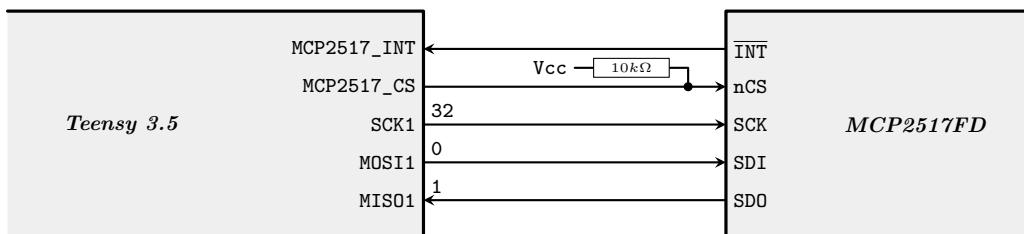

Figure 4 – Using SPI alternate pins on a Teensy 3.5

```
ACAN2517FD can (MCP2517_CS, SPI1, MCP2517_INT) ;
...
static const byte MCP2517_SCK = 32 ; // SCK input of MCP2517
static const byte MCP2517_SDI =  0 ; // SDI input of MCP2517
static const byte MCP2517_SDO =  1 ; // SDO output of MCP2517
...
void setup () {
  ...
  SPI1.setMOSI (MCP2517_SDI) ;
  SPI1.setMISO (MCP2517_SDO) ;
  SPI1.setSCK  (MCP2517_SCK) ;
  SPI1.begin () ;
  ...
  const uint32_t errorCode = can.begin (settings, [] { can.isr () ; }) ;
  ...
```

Note you can use the `SPI1.pinIsMOSI`, `SPI1.pinIsMISO`, and `SPI1.pinIsSCK` functions to check if the alternate pins you select are valid:

```
void setup () {
  ...
  Serial.print ("Using pin #") ;
  Serial.print (MCP2517_SDI) ;
  Serial.print (" for MOSI: ") ;
  Serial.println (SPI1.pinIsMOSI (MCP2517_SDI) ? "yes" : "NO!!!") ;
  Serial.print ("Using pin #") ;
  Serial.print (MCP2517_SDO) ;
  Serial.print (" for MISO: ") ;
  Serial.println (SPI1.pinIsMISO (MCP2517_SDO) ? "yes" : "NO!!!") ;
  Serial.print ("Using pin #") ;
  Serial.print (MCP2517_SCK) ;
  Serial.print (" for SCK: ") ;
  Serial.println (SPI1.pinIsSCK (MCP2517_SCK) ? "yes" : "NO!!!") ;
  SPI1.setMOSI (MCP2517_SDI) ;
  SPI1.setMISO (MCP2517_SDO) ;
  SPI1.setSCK  (MCP2517_SCK) ;
  SPI1.begin () ;
  ...
  const uint32_t errorCode = can.begin (settings, [] { can.isr () ; }) ;
  ...
```

7.3   Using alternate pins on an Adafruit Feather M0

Demo sketch: `LoopBackDemoAdafruitFeatherM0`.

See https://learn.adafruit.com/using-atsamd21-sercom-to-add-more-spi-i2c-serial-ports/overview doc-

ument that explains in details how configure and set alternate SPI pins on Adafruit Feather M0.

For example, the `LoopBackDemoAdafruitFeatherM0` sketch uses `SERCOM1` on an Adafruit Feather M0 as illustrated in figure 5.
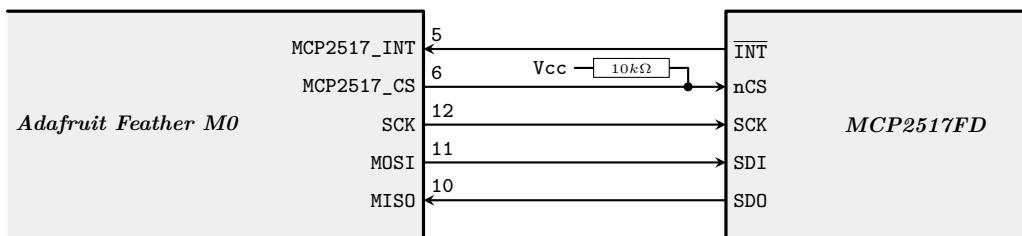

Figure 5 – Using SPI alternate pins on an Adafruit Feather M0

The configuration code is the following. Note you should call the `pinPeripheral` function **after** calling the `mySPI.begin` function.

```
#include <wiring_private.h>
...
static const byte MCP2517_SCK = 12 ; // SCK pin, SCK input of MCP2517FD
static const byte MCP2517_SDI = 11 ; // MOSI pin, SDI input of MCP2517FD
static const byte MCP2517_SDO = 10 ; // MISO pin, SDO output of MCP2517FD

SPIClass mySPI (&sercom1,
                MCP2517_SDO, MCP2517_SDI, MCP2517_SCK,
                SPI_PAD_0_SCK_3, SERCOM_RX_PAD_2);

static const byte MCP2517_CS  =  6 ; // CS input of MCP2517FD
static const byte MCP2517_INT =  5 ; // INT output of MCP2517FD
...
ACAN2517FD can (MCP2517_CS, mySPI, MCP2517_INT) ;
...
void setup () {
  ...
  mySPI.begin () ;
  pinPeripheral (MCP2517_SDI, PIO_SERCOM);
  pinPeripheral (MCP2517_SCK, PIO_SERCOM);
  pinPeripheral (MCP2517_SDO, PIO_SERCOM);
  ...
  const uint32_t errorCode = can.begin (settings, [] { can.isr () ; }) ;
  ...
```

7.4   Connecting to an ESP32

Demo sketches: `LoopBackDemoESP32` and `LoopBackESP32-intensive`. See also the ESP32 demo sketch `SPI_Multiple_Busses`.

Link: https://randomnerdtutorials.com/esp32-pinout-reference-gpios/

Two ESP32 SPI busses are available in Arduino, `HSPI` and `VSPI`. By default, Arduino SPI is `VSPI`. The ESP32 default pins are given in table 2.

Port	SCK	MOSI	MISO
VSPI	IO18	IO23	IO19
HSPI	IO14	IO13	IO12

Table 2 – ESP32 SPI default pins

7.4.1   Connecting `MCP2517_CS` and `MCP2517_INT`

For `MCP2517_CS`, you can use any port that can be configured as digital output. `ACAN2517FD` does not support hardware chip select. For `MCP2517_INT`, you can use any port that can be configured as digital input, as ESP32 provides interrupt capability on any input pin.

Note. `IO34` to `IO39` are input only pins, without internal pullup or pulldown. So you cannot use theses pins for `MCP2517_CS`. If you use one of theses pins for `MCP2517_INT`, you should add an external pullup resistor if you configure the $\overline{\text{INT}}$ pin as Open Drain (section 19.11.2 page 40).

7.4.2   Using `SPI`

Default `SPI` (i.e. `VSPI`) pins are: SCK=18, MISO=19, MOSI=23 (figure 6).
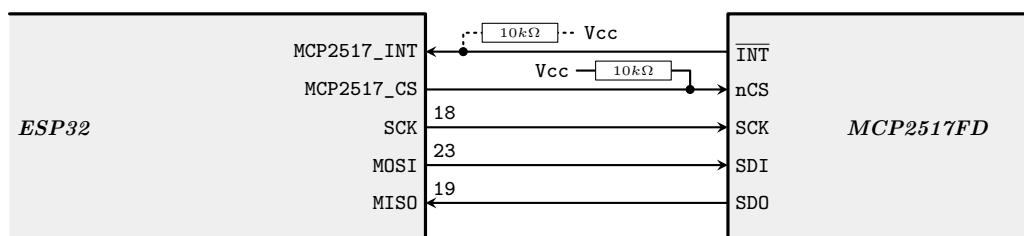

Figure 6 – Using VSPI default pins on an ESP32

You can change the default pins with additional arguments (up to three) for `SPI.begin` :

```
SPI.begin (SCK_PIN) ; // Uses MISO and MOSI default pins
```

or

```
SPI.begin (SCK_PIN, MISO_PIN) ; // Uses MOSI default pin
```

or

```
SPI.begin (SCK_PIN, MISO_PIN, MOSI_PIN) ;
```

Note that `SPI.begin` accepts a fourth argument, for `CS` pin. Do not use this feature with `ACAN2517FD`.

7.4.3   Using `HSPI`

The ESP32 demo sketch `SPI_Multiple_Busses` shows how to use both `HSPI` and `VSPI`. However for `ACAN2517FD`, we proceed in a slightly different way:

```
#include <SPI.h>
....
SPIClass hspi (HSPI) ;
ACAN2517FD can (MCP2517_CS, hspi, MCP2517_INT) ;
....
void setup () {
  ....
  hspi.begin () ; // You can also add parameters for not using default pins
```

```
   ....
}
```

You declare the `hspi` object before declaring the `can` object. You can change the `hspi` name, the important point is the `HSPI` argument that specifies the HSPI bus. Then, instead of using the `SPI` name, you use the `hspi` name in:

- `can` object declaration;

- in begin SPI instruction.

See the `LoopBackESP32-intensive` sketch for an example with `VSPI`.

7.5   Connection with no interrupt pin

See the `LoopBackDemoTeensy3xNoInt` and `LoopBackDemoESP32NoInt` sketches.

Note that not using an interruption is only valid if the message throughput is not too high. Received messages are recovered by polling, so the risk of MCP2517FD internal buffers overflowing is greater.
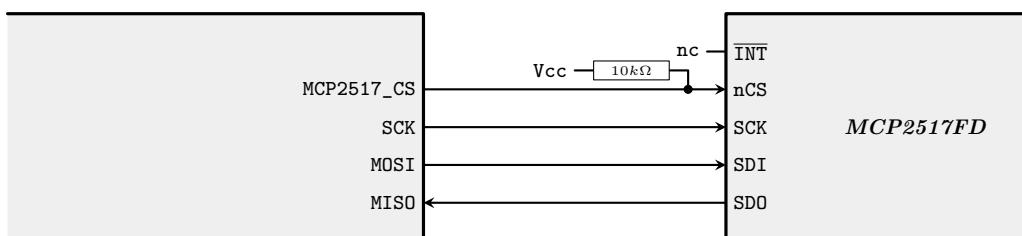

Figure 7 – Connection with no interrupt pin

For not using the interrupt signal, you should adapt your sketch as following:

1. the last argument of `can` constructor should be `255`, meaning no interrupt pin;

2. the second argument of `can.begin` should be `NULL` (no interrupt service routine);

3. in the `loop` function, you should call `can.poll` as often as possible.

```
ACAN2517FD can (MCP2517_CS, SPI, 255) ; // Last argument is 255 -> no interrupt pin

void setup () {
  ...
  const uint32_t errorCode = can.begin (settings, NULL) ; // ISR is null
  ...
}

void loop () {
  can.poll () ;
  ...
}
```

8 Clock configuration

The `MCP251xFD` Oscillator Block Diagram is given in figure 8. Microchip recommends using a 4, 40 or 20 MHz CLKIN, Crystal or Ceramic Resonator. *A PLL can be enabled to multiply a 4 MHz clock by 10 by setting the PLLEN bit. Setting the SCLKDIV bit divides the SYSCLK by 2.*[7]
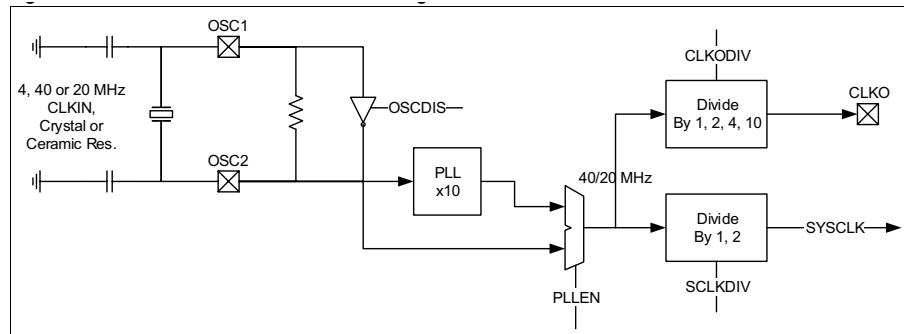

Figure 8 – `MCP251xFD` Oscillator Block Diagram (`DS20005678B`, figure 3.1 page 13)

The `ACAN2517FDSettings` class defines an enumerated type for specifying your settings:

```
class ACAN2517FDSettings {
  public: typedef enum {
    OSC_4MHz,
    OSC_4MHz_DIVIDED_BY_2,
    OSC_4MHz10xPLL,
    OSC_4MHz10xPLL_DIVIDED_BY_2,
    OSC_20MHz,
    OSC_20MHz_DIVIDED_BY_2,
    OSC_40MHz,
    OSC_40MHz_DIVIDED_BY_2
  } Oscillator ;
  ...
} ;
```

The first argument of the `ACAN2517FDSettings` constructor specifies the oscillator. For example, with a 4 MHz clock, the `ACAN2517FDSettings::OSC_4MHz10xPLL` setting leads to a 40 MHz `SYSCLK`.

The eight clock settings are given in the table 3. Note Microchip recommends a 40 MHz or 20 MHz `SYSCLK`. The `ACAN2517FDSettings` class has two accessors that return current settings: `oscillator()` and `sysClock()`.

Quartz	Oscillator parameter	SYSCLK
4 MHz	`OSC_4MHz`	4 MHz
4 MHz	`OSC_4MHz_DIVIDE_BY_2`	2 MHz
4 MHz	`OSC_4MHz10xPLL`	40 MHz
4 MHz	`OSC_4MHz10xPLL_DIVIDE_BY_2`	20 MHz
20 MHz	`OSC_20MHz`	20 MHz
20 MHz	`OSC_20MHz_DIVIDE_BY_2`	10 MHz
40 MHz	`OSC_40MHz`	40 MHz
40 MHz	`OSC_40MHz_DIVIDE_BY_2`	20 MHz

Table 3 – The `ACAN2517FD` oscillator selection

The `begin` function of `ACAN2517FD` library first configures the selected SPI with a frequency of 1 Mbit/s, for resetting the `MCP2517FD` and programming the `PLLEN` and `SCLKDIV` bits. Then SPI clock is set to a frequency

---

[7]DS20005678B, page 13.

equal to `SYSCLK / 2`, the maximum allowed frequency. More precisely, the SPI library of your microcontroller may adopt a lower frequency; for example, the maximum frequency of the Arduino Uno SPI is 8 Mbit/s.

Note that an incorrect setting may crash the `MCP2517FD` firmware (for example, enabling the PLL with a 20 MHz or 40 MHz quartz). In such case, no SPI communication can then be established, and in particular, the `MCP2517FD` cannot be reset by software. As the `MCP2517FD` has no `RESET` pin, the only way is to power off and power on the `MCP2517FD`.

9   Transmit FIFO

The transmit FIFO (see figure 1 page 5) is composed by:

- the *driver transmit FIFO*, whose size is positive or zero (default 16); you can change the default size by setting the `mDriverTransmitFIFOSize` property of your `settings` object;

- the *controller transmit FIFO*, whose size is between 1 and 32 (default 32); you can change the default size by setting the `mControllerTransmitFIFOSize` property of your `settings` object.

Having a *driver transmit FIFO* of zero size is valid; in this case, the FIFO must be considered both empty and full.

For sending a message throught the *Transmit FIFO*, call the `tryToSend` method with a message whose `idx` property is zero:

- if the *controller transmit FIFO* is not full, the message is appended to it, and `tryToSend` returns `true`;

- otherwise, if the *driver transmit FIFO* is not full, the message is appended to it, and `tryToSend` returns `true`; the interrupt service routine will transfer messages from *driver transmit FIFO* to the *controller transmit FIFO* when it becomes not full;

- otherwise, both FIFOs are full, the message is not stored and `tryToSend` returns `false`.

The transmit FIFO ensures sequentiality of emissions.

There are three other parameters you can override:

- `settings.mControllerTransmitFIFORetransmissionAttempts` is the number of retransmission attempts; by default, it is set to `UnlimitedNumber`; other values are `Disabled` and `ThreeAttempts`;

- `settings.mControllerTransmitFIFOPriority` is the priority of the transmit FIFO: between 0 (lowest priority) and 31 (highest priority); default value is 0;

- `settings.mControllerTransmitFIFOPayload` is the controller transmit FIFO object payload size; default value is `PAYLOAD_64`, enabled sending any CAN FD frame; see section 12 page 19.

The *controller transmit FIFO* is located in the `MCP2517FD` RAM. It requires 16 bytes for each message (see section 13 page 20).

9.1   The `driverTransmitBufferSize` method

The `driverTransmitBufferSize` method returns the allocated size of this driver transmit buffer, that is the value of `settings.mDriverTransmitBufferSize` when the `begin` method is called.

```
const uint32_t s = can.driverTransmitBufferSize () ;
```

9.2   The `driverTransmitBufferCount` method

The `driverTransmitBufferCount` method returns the current number of messages in the driver transmit buffer.

```
const uint32_t n = can.driverTransmitBufferCount () ;
```

9.3   The `driverTransmitBufferPeakCount` method

The `driverTransmitBufferPeakCount` method returns the peak value of message count in the driver transmit buffer

```
const uint32_t max = can.driverTransmitBufferPeakCount () ;
```

If the transmit buffer is full when `tryToSend` is called, the return value of this call is `false`. In such case, the following calls of `driverTransmitBufferPeakCount()` will return `driverTransmitBufferSize ()+1`.

So, when `driverTransmitBufferPeakCount()` returns a value lower or equal to `transmitBufferSize ()`, it means that calls to `tryToSend` have always returned `true`, and no overflow occurs on driver transmit buffer.

10   Transmit Queue (`TXQ`)

The *Transmit Queue* is handled by the `MCP2517FD`, its contents is located in its RAM. **It is not a FIFO.** *Messages inside the TXQ will be transmitted based on their ID. The message with the highest priority ID, lowest ID value will be transmitted first*[8].

By default, the *transmit queue* is disabled (its default size is 0); you can change the default size by setting the `mControllerTXQSize` property of your `settings` object. The maximum valid size is 32.

For sending a message throught the *transmit queue*, call the `tryToSend` method with a message whose `idx` property is 255:

- if the *transmit queue* size is not zero and if it is not full, the message is appended to it, and `tryToSend` returns `true`;

- otherwise, the message is not stored and `tryToSend` returns `false`.

There are three other parameters you can override:

- `inSettings.mControllerTXQBufferRetransmissionAttempts` is the number of retransmission attempts; by default, it is set to `UnlimitedNumber`; other values are `Disabled` and `ThreeAttempts`;

- `inSettings.mControllerTXQBufferPriority` is the priority of the TXQ buffer: between 0 (lowest priority) and 31 (highest priority); default value is 31;

- `inSettings.mControllerTXQBufferPayload` is the controller TXQ buffer object payload size; default value is `PAYLOAD_64`, enabled sending any CAN FD frame; see section 12 page 19.

The *transmit queue* is located in the `MCP2517FD` RAM. It requires 16 bytes for each message (see section 13 page 20).

---

[8]DS20005678B, section 4.5, page 28.

11 Receive FIFO

The receive FIFO (see figure 1 page 5) is composed by:

- the *driver receive FIFO*, whose size is positive (default 32); you can change the default size by setting the `mDriverReceiveFIFOSize` property of your `settings` object;

- the *controller receive FIFO*, whose size is between 1 and 32 (default 32); you can change the default size by setting the `mControllerReceiveFIFOSize` property of your `settings` object.

You can override the `mControllerReceiveFIFOPayload` value, which represents the controller receive FIFO object payload size; default value is `PAYLOAD_64`, enabled receiving any CAN FD frame. See section 12 page 19.

When an incoming message is accepted by a receive filter:

- if the *controller receive FIFO* is full, the message is lost;

- otherwise, it is stored in the *controller receive FIFO*.

Then, if the *driver receive FIFO* is not full, the message is transferred by the *interrupt service routine* from *controller receive FIFO* to the *driver receive FIFO*. So the *driver receive FIFO* never overflows, but *controller receive FIFO* may.

The `ACAN2517FD::available`, `ACAN2517FD::receive` and `ACAN2517FD::dispatchReceivedMessage` methods work only with the *driver receive FIFO*. As soon as it becomes not full, messages from *controller receive FIFO* are transferred by the *interrupt service routine*.

The receive FIFO ensures sequentiality of reception.

The *controller receive FIFO* is located in the `MCP2517FD` RAM. It requires 16 bytes for each message (see next section).

12 Payload size

Controller transmit FIFO, controller TXQ buffer and controller receive FIFO objects are stored in the internal `MCP2517FD` RAM. The size of each object depends on the setting applied to the corresponding FIFO or buffer.

By default, all FIFOs and buffer accept objects up to 64 data bytes. The size of each object is 72 bytes. As the internal `MCP2517FD` RAM has a capacity of 2048 bytes, only 28 objects are available, and they are allocated as follows:

- controller transmit FIFO (`mControllerTransmitFIFOSize` property): 4 objects;

- controller TXQ buffer (`mControllerTXQSize` property): no object;

- controller receive FIFO (`mControllerReceiveFIFOSize` property): 24 objects.

The details of RAM usage computation are presented in section 13 page 20.

Note the `ACAN2517` library[9] handles an `MCP2517FD` in CAN 2.0B mode. As CAN 2.0B frames contains at most 8 bytes, the size of each object is 16 bytes, allowing using up to 128 objects.

With the `mControllerTransmitFIFOPayload`, the `mControllerTXQBufferPayload` and the `mControllerReceiveFIFOPayload` properties, you can adjust the object size following your application requirements. The table 4 shows the possible values of these properties and the corresponding payload and object size.

---

[9]https://github.com/pierremolinaro/acan2517

By example, suppose your application always send data frames with no more than 24 bytes. You can set the `mControllerTransmitFIFOPayload` and `mControllerReceiveFIFOPayload` properties to `ACAN2517FDSettings::PAYLOAD_24`, leading to an object size equal to 32 bytes. If your application also receives data frames with no more than 24 bytes, you can also set the `mControllerReceiveFIFOPayload` property to `ACAN2517FDSettings::PAYLOAD_24`. All your objects require 32 bytes, allowing 64 objects in the `MCP2517FD` RAM. The benefit is you can now increase controller buffer sizes, for example:

- controller transmit FIFO (`mControllerTransmitFIFOSize` property): 16 objects;

- controller TXQ buffer (`mControllerTXQSize` property): 16 objects;

- controller receive FIFO (`mControllerReceiveFIFOSize` property): 32 objects.

Object Size specification	Payload	Object Size
`ACAN2517FDSettings::PAYLOAD_8`	Up to 8 bytes	16 bytes
`ACAN2517FDSettings::PAYLOAD_12`	Up to 12 bytes	20 bytes
`ACAN2517FDSettings::PAYLOAD_16`	Up to 16 bytes	24 bytes
`ACAN2517FDSettings::PAYLOAD_20`	Up to 20 bytes	28 bytes
`ACAN2517FDSettings::PAYLOAD_24`	Up to 24 bytes	32 bytes
`ACAN2517FDSettings::PAYLOAD_32`	Up to 32 bytes	40 bytes
`ACAN2517FDSettings::PAYLOAD_48`	Up to 48 bytes	56 bytes
`ACAN2517FDSettings::PAYLOAD_64`	Up to 64 bytes	72 bytes

Table 4 – `ACAN2517FD` object size from payload size specification

12.1 The `ACAN2517FDSettings::objectSizeForPayload` static method

```
uint32_t ACAN2517FDSettings::objectSizeForPayload (const PayloadSize inPayload) ;
```

This static method returns the object size for a given payload specification, following table 4.

13 RAM usage

The `MCP2517FD` contains a 2048 bytes RAM that is used to store message objects[10]. There are three different kinds of message objects:

- Transmit Message Objects used by the TXQ buffer;

- Transmit Message Objects used by the transmit FIFO;

- Receive Message Objects used by the receive FIFO.

There are six parameters that affect the required memory amount:

- the `mControllerTransmitFIFOSize` property sets the controller transmit FIFO object count;

- the `mControllerTransmitFIFOPayload` property defines the controller transmit FIFO object size;

- the `mControllerTXQSize` property sets the controller TXQ buffer object count;

- the `mControllerTXQBufferPayload` property defines the controller TXQ buffer object size;

---

[10]DS20005688B, section 3.3, page 63.

- the `mControllerReceiveFIFOSize` property sets the controller receive FIFO object count;

- the `mControllerReceiveFIFOPayload` property defines the controller receive FIFO object size.

The `ACAN2517FDSettings::ramUsage` method computes the required memory amount as follows:

```
uint32_t ACAN2517FDSettings::ramUsage (void) const {
  uint32_t r = 0 ;
//--- TXQ
  r += objectSizeForPayload(mControllerTXQBufferPayload) * mControllerTXQSize;
//--- Receive FIFO (FIFO #1)
  r += objectSizeForPayload(mControllerReceiveFIFOPayload) * mControllerReceiveFIFOSize;
//--- Send FIFO (FIFO #2)
  r += objectSizeForPayload(mControllerTransmitFIFOPayload) * mControllerTransmitFIFOSize;
//---
  return r ;
}
```

The `ACAN2517FD:begin` method checks the required memory amount is lower or equal than 2048 bytes. Otherwise, it raises the error code `kControllerRamUsageGreaterThan2048`.

You can also use the *MCP2517FD RAM Usage Calculations* Excel sheet from Microchip[11].

14 Sending frames: the `tryToSend` methods

There are two `ACAN2517FD::tryToSend` methods. The first one handles sending CAN 2.0B and CAN FD frames:

```
bool ACAN2517FD::tryToSend (const CANFDMessage & inMessage) ;
```

For convience, a second prototype is provided, which sends only CAN 2.0B frames:

```
bool ACAN2517FD::tryToSend (const CANMessage & inMessage) ;
```

```
  ...
  CANFDMessage message ;
  // Setup message
  const bool ok = can.tryToSend (message) ;
  ...
```

You call the `tryToSend` method for sending a message in the CAN network. Note this function returns before the message is actually sent; this function only appends the message to a transmit buffer.

The `idx` field of the message specifies the transmit buffer:

- 0 for the transmit FIFO (section 9 page 17) ;

- 255 for the transmit Queue (section 10 page 18).

The `tryToSend` method returns:

- `false` if the message responds `false` to the `isValid` method (see section 5.4 page 10), or if its `len` property has a value greater than the corresponding buffer payload; an invalid message is never submitted to a transmit buffer;

- otherwise, if the message responds `true` to the `isValid` method:

---

[11]http://ww1.microchip.com/downloads/en/DeviceDoc/MCP2517FD%20RAM%20Usage%20Calculations%20-%20UG.xlsx

– **true** if the message has been successfully transmitted to the transmit buffer; note that does not mean that the CAN frame has been actually sent;

– **false** if the message has not been successfully transmitted to the transmit buffer, it was full.

So it is wise to systematically test the returned value.

A way is to use a global variable to note if the message has been successfully transmitted to driver transmit buffer. For example, for sending a message every 2 seconds:

```
static uint32_t gSendDate = 0 ;

void loop () {
  if (gSendDate < millis ()) {
    CANFDMessage message ;
    // Initialize message properties
    const bool ok = can.tryToSend (message) ;
    if (ok) {
      gSendDate += 2000 ;
    }
  }
}
```

An other hint to use a global boolean variable as a flag that remains **true** while the message has not been sent.

```
static bool gSendMessage = false ;

void loop () {
  ...
  if (frame_should_be_sent) {
    gSendMessage = true ;
  }
  ...
  if (gSendMessage) {
    CANMessage message ;
    // Initialize message properties
    const bool ok = can.tryToSend (message) ;
    if (ok) {
      gSendMessage = false ;
    }
  }
  ...
}
```

15 Retrieving received messages using the **receive** method

There are two ways for retrieving received messages :

- using the **receive** method, as explained in this section;

- using the **dispatchReceivedMessage** method (see).

This is a basic example:

```
void loop () {
  CANFDMessage message ;
  if (can.receive (message)) {
```

```
    // Handle received message
  }
  ...
}
```

The `receive` method:

- returns `false` if the driver receive buffer is empty, `message` argument is not modified;

- returns `true` if a message has been has been removed from the driver receive buffer, and the `message` argument is assigned.

You need to manually dispatch the received messages. If you did not provide any receive filter, you should check the `rtr` bit (remote or data frame?), the `ext` bit (standard or extended frame), and the `id` (identifier value). The following snippet dispatches three messages:

```
void loop () {
  CANFDMessage message ;
  if (can.receive (message)) {
    if (!message.rtr && message.ext && (message.id == 0x123456)) {
      handle_myMessage_0 (message) ; // Extended data frame, id is 0x123456
    }else if (!message.rtr && !message.ext && (message.id == 0x234)) {
      handle_myMessage_1 (message) ;  // Standard data frame, id is 0x234
    }else if (message.rtr && !message.ext && (message.id == 0x542)) {
      handle_myMessage_2 (message) ;  // Standard remote frame, id is 0x542
    }
  }
  ...
}
```

The `handle_myMessage_0` function has the following header:

```
void handle_myMessage_0 (const CANFDMessage & inMessage) {
  ...
}
```

So are the header of the `handle_myMessage_1` and the `handle_myMessage_2` functions.

15.1   Driver receive buffer size

By default, the driver receive buffer size is 24. You can change it by setting the `mReceiveBufferSize` property of `settings` variable before calling the `begin` method:

```
ACAN2517FDSettings settings (ACAN2517FDSettings::OSC_4MHz10xPLL,
                             125 * 1000, ACAN2517FDSettings::DATA_BITRATE_x4) ;
settings.mReceiveBufferSize = 100 ;
const uint32_t errorCode = can.begin (settings, [] { can.isr () ; }) ;
...
```

As the size of `CANFDMessage` class is 72 bytes, the actual size of the driver receive buffer is the value of `settings.mReceiveBufferSize * 72`.

15.2   The `receiveBufferSize` method

The `receiveBufferSize` method returns the size of the driver receive buffer, that is the value of the `mReceiveBufferSize` property of `settings` variable when the the `begin` method is called.

```
const uint32_t s = can.receiveBufferSize () ;
```

15.3 The `receiveBufferCount` method

The `receiveBufferCount` method returns the current number of messages in the driver receive buffer.

```
const uint32_t n = can.receiveBufferCount () ;
```

15.4 The `receiveBufferPeakCount` method

The `receiveBufferPeakCount` method returns the peak value of message count in the driver receive buffer.

```
const uint32_t max = can.receiveBufferPeakCount () ;
```

Note the driver receive buffer can overflow, if messages are not retrieved (by calling the `receive` or the `dispatchReceivedMessage` methods). If an overflow occurs, further calls of `can.receiveBufferPeakCount ()` return `can.receiveBufferSize ()+1`.

16 Acceptance filters

Note. The acceptance filters implemented in the `ACAN2517` library, that handles a `MCP2517FD` CAN Controller in the CAN 2.0B mode[12], are almost identical, they differ only from the prototype of the callback routine.

If you invoke the `ACAN2517FD.begin` method with two arguments, it configures the `MCP2517FD` for receiving all messages.

```
const uint32_t errorCode = can.begin (settings, [] { can.isr () ; }) ;
```

If you want to define receive filters, you have to set up an `MCP2517FDFilters` instance object, and pass it as third argument of the `ACAN2517FD.begin` method:

```
MCP2517FDFilters filters ;
... // Append filters
const uint32_t errorCode = can.begin (settings, [] { can.isr () ; }, filters) ;
...
```

16.1 An example

Sample sketch: the `LoopBackDemoTeensy3xWithFilters` sketch is an example of filter definition.

```
MCP2517FDFilters filters ;
```

First, you instanciate an `MCP2517FDFilters` object. It represents an empty list of filters. So, if you do not append any filter, `can.begin (settings, [] { can.isr () ; }, filters)` configures the controller in such a way that no messages can be received.

```
// Filter #0: receive standard frame with identifier 0x123
  filters.appendFrameFilter (kStandard, 0x123, receiveFromFilter0) ;
// Filter #1: receive extended frame with identifier 0x12345678
  filters.appendFrameFilter (kExtended, 0x12345678, receiveFromFilter1) ;
```

You define the filters sequentially, with the four methods: `appendPassAllFilter`, `appendFormatFilter`, `appendFrameFilter`, `appendFilter`. Theses methods have as last argument an optional callback routine, that is called by the `dispatchReceivedMessage` method (see section 17 page 27).

The `appendFrameFilter` defines a filter that matches for an extended or standard identifier of a given value.

---

[12]https://github.com/pierremolinaro/acan2517

You can define up to 32 filters. Filter definition registers are outside the `MCP2517FD` RAM, so defining filter does not restrict the receive and transmit buffer sizes. Note that `MCP2517FD` filter does not allow to establish a filter based on the data / remote information.

```
// Filter #2: receive standard frame with identifier 0x3n4 (0 <= n <= 15)
  filters.appendFilter (kStandard, 0x70F, 0x304, receiveFromFilter2) ;
```

The `appendFilter` defines a filter that matches for an identifier that matches the condition:

$$\text{identifier} \ \& \ \text{0x70F} == \text{0x304}$$

The `kStandard` argument constraints to accept only standard frames. So the accepted standard identifiers are `0x304, 0x314, 0x324, ..., 0x3E4, 0x3F4`.

```
//--------------------------------- Filters ok ?
  if (filters.filterStatus () != MCP2517FDFilters::kFiltersOk) {
    Serial.print ("Error filter ") ;
    Serial.print (filters.filterErrorIndex ()) ;
    Serial.print (": ") ;
    Serial.println (filters.filterStatus ()) ;
  }
```

Filter definitions can have error(s), you can check error kind with the `filterStatus` method. If it returns a value different than `MCP2517FDFilters::kFiltersOk`, there is at least one error: only the last one is reported, and the `filterErrorIndex` returns the corresponding filter index. Note this does not check the number of filters is lower or equal than 32.

```
  const uint32_t errorCode = can.begin (settings, [] { can.isr () ; }, filters) ;
```

The `begin` method checks the filter definition:

- it raises the `kMoreThan32Filters` error if more than 32 filters are defined;

- it raises the `kFilterDefinitionError` error if one or more filter definitions are erroneous (that is if `filterStatus` returns a value different than `MCP2517FDFilters::kFiltersOk`).

16.2 The `appendPassAllFilter` method

```
  void MCP2517FDFilters::appendPassAllFilter (const ACANFDCallBackRoutine inCallBackRoutine) ;
```

This defines a filter that accepts all (standard / extended, remote / data) frames.

If used, this filter must be the last one: as the `MCP2517FD` tests the filters sequentially, the following filters will never match.

16.3 The `appendFormatFilter` method

```
  void MCP2517FDFilters::appendFormatFilter (const tFrameFormat inFormat,
                                             const ACANFDCallBackRoutine inCallBackRoutine) ;
```

This defines a filter that accepts:

- if `inFormat` is equal to `kStandard`, all standard remote frames and all standard data frames;

- if `inFormat` is equal to `kExtended`, all extended remote frames and all extended data frames.

16.4   The `appendFrameFilter` method

```
void MCP2517FDFilters::appendFrameFilter (const tFrameFormat inFormat,
                                          const uint32_t inIdentifier,
                                          const ACANFDCallBackRoutine inCallBackRoutine) ;
```

This defines a filter that accepts:

- if `inFormat` is equal to `kStandard`, all standard remote frames and all standard data frames with a given identifier;

- if `inFormat` is equal to `kExtended`, all extended remote frames and all extended data frames with a given identifier.

If `inFormat` is equal to `kStandard`, the `inIdentifier` should be lower or equal to `0x7FF`. Otherwise, `settings.filterStatus` () returns the `kStandardIdentifierTooLarge` error.

If `inFormat` is equal to `kExtended`, the `inIdentifier` should be lower or equal to `0x1FFFFFFF`. Otherwise, `settings.filterStatus` () returns the `kExtendedIdentifierTooLarge` error.

16.5   The `appendFilter` method

```
void MCP2517FDFilters::appendFilter (const tFrameFormat inFormat,
                                     const uint32_t inMask,
                                     const uint32_t inAcceptance,
                                     const ACANFDCallBackRoutine inCallBackRoutine) ;
```

The `inMask` and `inAcceptance` arguments defines a filter that accepts frame whose identifier verifies:

$$\text{identifier} \ \& \ \text{inMask} == \text{inAcceptance}$$

The `inFormat` filters standard (if `inFormat` is equal to `kStandard`) frames, or extended ones (if `inFormat` is equal to `kExtended`).

Note that `inMask` and `inAcceptance` arguments should verify:

$$\text{inAcceptance} \ \& \ \text{inMask} == \text{inAcceptance}$$

Otherwise, `settings.filterStatus` () returns the `kInconsistencyBetweenMaskAndAcceptance` error.

If `inFormat` is equal to `kStandard`:

- the `inAcceptance` should be lower or equal to `0x7FF`; Otherwise, `settings.filterStatus` () returns the `kStandardAcceptanceTooLarge` error;

- the `inMask` should be lower or equal to `0x7FF`; Otherwise, `settings.filterStatus` () returns the `kStandardMaskTooLarge` error.

If `inFormat` is equal to `kExtended`:

- the `inAcceptance` should be lower or equal to `0x1FFFFFFF`; Otherwise, `settings.filterStatus` () returns the `kExtendedAcceptanceTooLarge` error;

- the `inMask` should be lower or equal to `0x1FFFFFFF`; Otherwise, `settings.filterStatus` () returns the `kExtendedMaskTooLarge` error.

17 The `dispatchReceivedMessage` method

Sample sketch: the `LoopBackDemoTeensy3xWithFilters` shows how using the `dispatchReceivedMessage` method.

Instead of calling the `receive` method, call the `dispatchReceivedMessage` method in your `loop` function. It calls the call back function associated with the matching filter.

If you have not defined any filter, do not use this function, call the `receive` method.

```
void loop () {
  can.dispatchReceivedMessage () ; // Do not use can.receive any more
  ...
}
```

The `dispatchReceivedMessage` method handles one message at a time. More precisely:

- if it returns `false`, the driver receive buffer was empty;

- if it returns `true`, the driver receive buffer was not empty, one message has been removed and dispatched.

So, the return value can used for emptying and dispatching all received messages:

```
void loop () {
  while (can.dispatchReceivedMessage ()) {
  }
  ...
}
```

If a filter definition does not name a call back function, the corresponding messages are lost.

The `dispatchReceivedMessage` method has an optional argument – `NULL` by default: a function name. This function is called for every message that pass the receive filters, with an argument equal to the matching filter index:

```
void filterMatchFunction (const uint32_t inFilterIndex) {
  ...
}

void loop () {
  can.dispatchReceivedMessage (filterMatchFunction) ;
  ...
}
```

You can use this function for maintaining statistics about receiver filter matches.

18 The `ACAN2517FD::begin` method reference

18.1 The prototypes

```
uint32_t ACAN2517FD::begin (const ACAN2517FDSettings & inSettings,
                            void (* inInterruptServiceRoutine) (void)) ;
```

This prototype has two arguments, a `ACAN2517FDSettings` instance that defines the settings, and the interrupt service routine, that can be specified by a lambda expression or a function (see). It configures the controller in such a way that all messages are received (*pass-all* filter).

```
uint32_t ACAN2517FD::begin (const ACAN2517FDSettings & inSettings,
                            void (* inInterruptServiceRoutine) (void),
                            const MCP2517FDFilters & inFilters) ;
```

The second prototype has a third argument, an instance of `MCP2517FDFilters` class that defines the receive filters.

18.2   Defining explicitly the interrupt service routine

In this document, the *interrupt service routine* is defined by a lambda expression:

```
const uint32_t errorCode = can.begin (settings, [] { can.isr () ; }) ;
```

Instead of a lambda expression, you are free to define the *interrupt service routine* as a function:

```
void canISR () {
  can.isr () ;
}
```

And you pass `canISR` as argument to the `begin` method:

```
const uint32_t errorCode = can.begin (settings, canISR) ;
```

18.3   The error code

The `ACAN2517FD::begin` method returns an error code. The value `0` denotes no error. Otherwise, you consider every bit as an error flag, as described in table 5. An error code could report several errors. The `ACAN2517FD` class defines static constants for naming errors.

Bit	Code	Static constant Name	Link
0	0x1	kRequestedConfigurationModeTimeOut	section 18.3.1 page 28

Table 5 – The `ACAN2517FD::begin` method error code bits

18.3.1   kRequestedConfigurationModeTimeOut

The `ACAN2517FD::begin` method first configures SPI with a 1 Mbit/s clock, and then requests the configuration mode. This error is raised when the `LCP2517FD` does not reach the configuration mode with 2ms. It means that the `MCP2517FD` cannot be accessed via SPI.

18.3.2   kReadBackErrorWith1MHzSPIClock

Then, the `ACAN2517FD::begin` method checks accessibility by writing and reading back 32-bit values at the first `MCP2517FD` RAM address (`0x400`). The values are $1 << n$, with $0 \leqslant n \leqslant 31$. This error is raised when the read value is different from the written one. It means that the `MCP2517FD` cannot be accessed via SPI.

18.3.3   kTooFarFromDesiredBitRate

This error occurs when the `mArbitrationBitRateClosedToDesiredRate` property of the `settings` object is `false`. This means that the `ACAN2517FDSettings` constructor cannot compute a CAN bit configuration close enough to the desired bit rate. For example:

```
void setup () {
  ACAN2517FDSettings settings (ACAN2517FDSettings::OSC_4MHz10xPLL,
                              1, ACAN2517FDSettings::DATA_BITRATE_x1) ; // 1 bit/s !!!
  // Here, settings.mArbitrationBitRateClosedToDesiredRate is false
  const uint32_t errorCode = can.begin (settings, [] { can.isr () ; }) ;
  // Here, errorCode contains ACAN2517FD::kCANBitConfigurationTooFarFromDesiredBitRate
}
```

18.3.4   kInconsistentBitRateSettings

The `ACAN2517FDSettings` constructor always returns consistent bit rate settings – even if the settings provide a bit rate too far away the desired bit rate. So this error occurs only when you have changed the CAN bit properties (`mBitRatePrescaler`, `mPropagationSegment`, `mArbitrationPhaseSegment1`, `mArbitrationPhaseSegment2`, `mArbitrationSJW`), and one or more resulting values are inconsistent. See section 19.2 page 36.

18.3.5   kINTPinIsNotAnInterrupt

The pin you provide for handling the `MCP2517FD` interrupt has no interrupt capability.

18.3.6   kISRIsNull

The interrupt service routine argument is `NULL`, you should provide a valid function.

18.3.7   kFilterDefinitionError

`settings.filterStatus()` returns a value different than `MCP2517FDFilters::kFiltersOk`, meaning that one or more filters are erroneous. See section 16.1 page 24.

18.3.8   kMoreThan32Filters

You have defined more than 32 filters. `MCP2517FD` cannot handle more than 32 filters.

18.3.9   kControllerReceiveFIFOSizeIsZero

You have assigned 0 to `settings.mControllerReceiveFIFOSize`. The *controller receive FIFO size* should be greater than 0.

18.3.10 `kControllerReceiveFIFOSizeGreaterThan32`

You have assigned a value greater than 32 to `settings.mControllerReceiveFIFOSize`. The *controller receive FIFO size* should be lower or equal than 32.

18.3.11 `kControllerTransmitFIFOSizeIsZero`

You have assigned 0 to `settings.mControllerTransmitFIFOSize`. The *controller transmit FIFO size* should be greater than 0.

18.3.12 `kControllerTransmitFIFOSizeGreaterThan32`

You have assigned a value greater than 32 to `settings.mControllerTransmitFIFOSize`. The *controller transmit FIFO size* should be lower or equal than 32.

18.3.13 `kControllerRamUsageGreaterThan2048`

The configuration you have defined requires more than 2048 bytes of `MCP2517FD` internal RAM. See section 13 page 20.

18.3.14 `kControllerTXQPriorityGreaterThan31`

You have assigned a value greater than 31 to `settings.mControllerTXQBufferPriority`. The *controller transmit FIFO size* should be lower or equal than 31.

18.3.15 `kControllerTransmitFIFOPriorityGreaterThan31`

You have assigned a value greater than 31 to `settings.mControllerTransmitFIFOPriority`. The *controller transmit FIFO size* should be lower or equal than 31.

18.3.16 `kControllerTXQSizeGreaterThan32`

You have assigned a value greater than 32 to `settings.mControllerTXQSize`. The *controller transmit FIFO size* should be lower than 32.

18.3.17 `kRequestedModeTimeOut`

During configuration by the `ACAN2517FD::begin` method, the `MCP2517FD` is in the *configuration* mode. At this end of this process, the mode specified by the `inSettings.mRequestedMode` value is requested. The switch to this mode is not immediate, a register is repetitively read for checking the switch is done. This error is raised if the switch is not completed within a delay between 1 ms and 2 ms.

18.3.18 `kX10PLLNotReadyWithin1MS`

You have requested the `QUARTZ_4MHz10xPLL` oscillator mode, enabling the 10x PLL. The `ACAN2517FD::begin` method waits during 2ms the PLL to be locked. This error is raised when the PLL is not locked within 2 ms.

18.3.19 kReadBackErrorWithFullSpeedSPIClock

After the oscillator configuration has been established, the `ACAN2517FD::begin` method configures the SPI at its full speed (`SYSCLK/2`, and checks accessibility by writing and reading back 32 32-bit values at the first `MCP2517FD` RAM address (`0x400`). The 32 used values are $1 << n$, with $0 \leqslant n \leqslant 31$. This error is raised when the read value is different from the written one.

18.3.20 kISRNotNullAndNoIntPin

This error occurs when you have no `INT` pin, and a not-null interrupt service routine:

```
ACAN2517 can (MCP2517_CS, SPI, 255) ; // Last argument is 255 -> no interrupt pin

void setup () {
  ...
  const uint32_t errorCode = can.begin (settings, [] { can.isr () ; }) ; // ISR is not null
  ...
}
```

Interrupt service routine should be `NULL` if no `INT` pin is defined:

```
ACAN2517 can (MCP2517_CS, SPI, 255) ; // Last argument is 255 -> no interrupt pin

void setup () {
  ...
  const uint32_t errorCode = can.begin (settings, NULL) ; // Ok, ISR is null
  ...
}
```

See the `LoopBackDemoTeensy3xNoInt` and `LoopBackDemoESP32NoInt` sketches.

19 ACAN2517FDSettings class reference

Note. The `ACAN2517FDSettings` class is not Arduino specific. You can compile it on your desktop computer with your favorite C++ compiler. In the https://github.com/pierremolinaro/acan2517FD-dev GitHub repository, a command line tool is defined for exploring all CAN arbitration bit rates from 1 bit/s to 1 Mbit/s. It also checks that computed CAN bit decompositions are all consistent, even if they are too far from the desired baud rate.

19.1 The ACAN2517FDSettings constructor: computation of the CAN bit settings

The constructor of the `ACAN2517FDSettings` has three mandatory arguments: the oscillator frequency, the desired arbitration bit rate, and the data bit rate factor. It tries to compute the CAN bit settings for theses bit rates. If it succeeds, the constructed object has its `mArbitrationBitRateClosedToDesiredRate` property set to `true`, otherwise it is set to `false`. For example, for an 1 Mbit/s arbitration bit rate and an 8 Mbit/s data bit rate:

```
void setup () {
 // Arbitration bit rate: 1 Mbit/s, data bit rate: 8 Mbit/s
  ACAN2517FDSettings settings (ACAN2517FDSettings::OSC_4MHz10xPLL,
                               1 * 1000 * 1000, ACAN2517FDSettings::DATA_BITRATE_x8) ;
  // Here, settings.mArbitrationBitRateClosedToDesiredRate is true
  ...
}
```

Note the data bit rate is not defined by its frequency, but by its multiplicative factor from arbitration bit rate. If you want a single bit rate, use `ACAN2517FDSettings::DATA_BITRATE_x1` as data bit rate factor.

Of course, with a 40 MHz or 20 MHz `SYSCLK`, CAN bit computation always succeeds for classical arbitration bit rates: 1 Mbit/s, 500 kbit/s, 250 kbit/s, 125 kbit/s. With a 40 MHz `SYSCLK`, there are 184 exact arbitration / data bit rate combinations (table 6 page 32), and 178 with a 20 MHz `SYSCLK` (table 7 page 33). Note a 8 MHz data bit rate cannot be performed with a 20 MHz `SYSCLK`. By "exact", we mean that arbitration bit rate and data bit rate are both exactly integer values. There is no such combination for data bit rate factors `3x`, `6x`, `7x`.

Arbitration Bit Rate	Valid Data Rate factors
500 bit/s	1x 8x
625 bit/s	1x 8x
640 bit/s	1x
800 bit/s	1x 5x 8x
1 kbit/s	1x 4x 5x 8x
1250 bit/s	1x 4x 5x 8x
1280 bit/s	1x 5x
1600 bit/s	1x 4x 5x 8x
2 kbit/s	1x 2x 4x 5x 8x
2500 bit/s	1x 2x 4x 5x 8x
2560 bit/s	1x 5x
3125 bit/s	1x 2x 4x 5x 8x
3200 bit/s	1x 2x 4x 5x
4 kbit/s	1x 2x 4x 5x 8x
5 kbit/s	1x 2x 4x 5x 8x
6250 bit/s	1x 2x 4x 5x 8x
6400 bit/s	1x 2x 5x
8 kbit/s	1x 2x 4x 5x 8x
10 kbit/s	1x 2x 4x 5x 8x
12500 bit/s	1x 2x 4x 5x 8x
12800 bit/s	1x 5x
15625 bit/s	1x 2x 4x 5x 8x
16 kbit/s	1x 2x 4x 5x
20 kbit/s	1x 2x 4x 5x 8x
25 kbit/s	1x 2x 4x 5x 8x
31250 bit/s	1x 2x 4x 5x 8x
32 kbit/s	1x 2x 5x
40 kbit/s	1x 2x 4x 5x 8x
50 kbit/s	1x 2x 4x 5x 8x
62500 bit/s	1x 2x 4x 5x 8x
64 kbit/s	1x 5x
78125 bit/s	1x 2x 4x 8x
80 kbit/s	1x 2x 4x 5x
100 kbit/s	1x 2x 4x 5x 8x
125 kbit/s	1x 2x 4x 5x 8x
156250 bit/s	1x 2x 4x 8x
160 kbit/s	1x 2x 5x
200 kbit/s	1x 2x 4x 5x 8x
250 kbit/s	1x 2x 4x 5x 8x
312500 bit/s	1x 2x 4x 8x
320 kbit/s	1x 5x
400 kbit/s	1x 2x 4x 5x
500 kbit/s	1x 2x 4x 5x 8x
625 kbit/s	1x 2x 4x 8x
800 kbit/s	1x 2x 5x
1000 kbit/s	1x 2x 4x 5x 8x

Table 6 – 40 MHz `SYSCLK`: the 184 exact bit rates

But this does not mean there is no possibility to get such data bit rates factors. For example, we can have a data

Arbitration Bit Rate	Valid Data Rate factors
250 bit/s	1x 8x
320 bit/s	1x
400 bit/s	1x 5x 8x
500 bit/s	1x 4x 5x 8x
625 bit/s	1x 4x 5x 8x
640 bit/s	1x 5x
800 bit/s	1x 4x 5x 8x
1 kbit/s	1x 2x 4x 5x 8x
1250 bit/s	1x 2x 4x 5x 8x
1280 bit/s	1x 5x
1600 bit/s	1x 2x 4x 5x
2 kbit/s	1x 2x 4x 5x 8x
2500 bit/s	1x 2x 4x 5x 8x
3125 bit/s	1x 2x 4x 5x 8x
3200 bit/s	1x 2x 5x
4 kbit/s	1x 2x 4x 5x 8x
5 kbit/s	1x 2x 4x 5x 8x
6250 bit/s	1x 2x 4x 5x 8x
6400 bit/s	1x 5x
8 kbit/s	1x 2x 4x 5x
10 kbit/s	1x 2x 4x 5x 8x
12500 bit/s	1x 2x 4x 5x 8x
15625 bit/s	1x 2x 4x 5x 8x
16 kbit/s	1x 2x 5x
20 kbit/s	1x 2x 4x 5x 8x
25 kbit/s	1x 2x 4x 5x 8x
31250 bit/s	1x 2x 4x 5x 8x
32 kbit/s	1x 5x
40 kbit/s	1x 2x 4x 5x
50 kbit/s	1x 2x 4x 5x 8x
62500 bit/s	1x 2x 4x 5x 8x
78125 bit/s	1x 2x 4x 8x
80 kbit/s	1x 2x 5x
100 kbit/s	1x 2x 4x 5x 8x
125 kbit/s	1x 2x 4x 5x 8x
156250 bit/s	1x 2x 4x 8x
160 kbit/s	1x 5x
200 kbit/s	1x 2x 4x 5x
250 kbit/s	1x 2x 4x 5x 8x
312500 bit/s	1x 2x 4x 8x
400 kbit/s	1x 2x 5x
500 kbit/s	1x 2x 4x 5x 8x
625 kbit/s	1x 2x 4x 8x
800 kbit/s	1x 5x
1000 kbit/s	1x 2x 4x 5x

Table 7 – 20 MHz `SYSCLK`: the 178 exact bit rates

bit rate of 4 Mbit/s, and an arbitration bit rate of 4/7 Mbit/s = 571 428 kbit/s:

```
void setup () {
  ...
  ACAN2517FDSettings settings (ACAN2517FDSettings::OSC_4MHz10xPLL,
                               571428, ACAN2517FDSettings::DATA_BITRATE_x7) ;
  Serial.print ("mArbitrationBitRateClosedToDesiredRate: ") ;
  Serial.println (settings.mArbitrationBitRateClosedToDesiredRate) ; // 1 (--> is true)
  Serial.print ("Actual Arbitration Bit Rate: ") ;
```

```
    Serial.println (settings.actualArbitrationBitRate ()) ; //  571428 bit/s
    Serial.print ("distance: ") ;
    Serial.println (settings.ppmFromDesiredArbitrationBitRate ()) ; // 1 ppm= 0,0001 %
    Serial.print ("Actual Data Bit Rate: ") ;
    Serial.println (settings.actualDataBitRate ()) ; //   4 Mbit/s
    ...
}
```

Due to integer computations, and the distance from desired arbitration bit rate is 1 ppm. "ppm" stands for "part-per-million", and $1\ \mathtt{ppm} = 10^{-6}$. In other words, $10,000\ \mathtt{ppm} = 1\%$.

By default, a desired bit rate is accepted if the distance from the computed actual bit rate is lower or equal to $1,000\ \mathtt{ppm} = 0.1\ \%$. You can change this default value by adding your own value as fourth argument of `ACAN2517FDSettings` constructor. Foe example, with an arbitration bit rate equal to 727 kbit/s:

```
void setup () {
  ...
  ACAN2517FDSettings settings (ACAN2517FDSettings::OSC_4MHz10xPLL,
                               727 * 1000, ACAN2517FDSettings::DATA_BITRATE_x1,
                               100) ; // 100 ppm
  Serial.print ("mArbitrationBitRateClosedToDesiredRate: ") ;
  Serial.println (settings.mArbitrationBitRateClosedToDesiredRate) ; // 0 (--> is false)
  Serial.print ("actual arbitration bit rate: ") ;
  Serial.println (settings.actualArbitrationBitRate ()) ; //  727272 bit/s
  Serial.print ("distance: ") ;
  Serial.println (settings.ppmFromDesiredArbitrationBitRate ()) ; // 375 ppm
  ...
}
```

The fourth argument does not change the CAN bit computation, it only changes the acceptance test for setting the `mArbitrationBitRateClosedToDesiredRate` property. For example, you can specify that you want the computed actual bit to be exactly the desired bit rate:

```
void setup () {
  ...
  ACAN2517FDSettings settings (ACAN2517FDSettings::OSC_4MHz10xPLL,
                               500 * 1000, ACAN2517FDSettings::DATA_BITRATE_x1,
                               0) ; // Max distance is 0 ppm
  Serial.print ("mArbitrationBitRateClosedToDesiredRate: ") ;
  Serial.println (settings.mArbitrationBitRateClosedToDesiredRate) ; // 1 (--> is true)
  Serial.print ("actual arbitration bit rate: ") ;
  Serial.println (settings.actualArbitrationBitRate ()) ; //  500,000 bit/s
  Serial.print ("distance: ") ;
  Serial.println (settings.ppmFromDesiredArbitrationBitRate ()) ; // 0 ppm
  ...
}
```

In any way, the bit rate computation always gives a consistent result, resulting an actual arbitration / data bit rates closest from the desired bit rate. For example, we query a 423 kbit/s arbitration bit rate, and a 423 kbit/s * 3 = 1 269 kbit/s data bit rates:

```
void setup () {
  ...
  ACAN2517FDSettings settings (ACAN2517FDSettings::OSC_4MHz10xPLL,
                               423 * 1000, ACAN2517FDSettings::DATA_BITRATE_x6) ;
  Serial.print ("mArbitrationBitRateClosedToDesiredRate: ") ;
  Serial.println (settings.mArbitrationBitRateClosedToDesiredRate) ; // 0 (--> is false)
  Serial.print ("Actual Arbitration Bit Rate: ") ;
  Serial.println (settings.actualArbitrationBitRate ()) ; //  416 666 bit/s
  Serial.print ("Actual Data Bit Rate: ") ;
```

```
    Serial.println (settings.actualDataBitRate ()) ; //  1 250 kbit/s
    Serial.print ("distance: ") ;
    Serial.println (settings.ppmFromDesiredArbitrationBitRate ()) ; // 14972 ppm
    ...
}
```

The resulting bit rates settings are far from the desired values, the CAN bit decomposition is consistent. You can get its details:

```
void setup () {
  ...
  ACAN2517FDSettings settings (ACAN2517FDSettings::OSC_4MHz10xPLL,
                               423 * 1000, ACAN2517FDSettings::DATA_BITRATE_x6) ;
  Serial.print ("mArbitrationBitRateClosedToDesiredRate: ") ;
  Serial.println (settings.mArbitrationBitRateClosedToDesiredRate) ; // 0 (--> is false)
  Serial.print ("Actual Arbitration Bit Rate: ") ;
  Serial.println (settings.actualArbitrationBitRate ()) ; //  416 666 bit/s
  Serial.print ("Actual Data Bit Rate: ") ;
  Serial.println (settings.actualDataBitRate ()) ; //  1 250 kbit/s
  Serial.print ("distance: ") ;
  Serial.println (settings.ppmFromDesiredArbitrationBitRate ()) ; // 14972 ppm
  Serial.print ("Bit rate prescaler: ") ;
  Serial.println (settings.mBitRatePrescaler) ; // BRP = 2
  Serial.print ("Arbitration Phase segment 1: ") ;
  Serial.println (settings.mArbitrationPhaseSegment1) ; // PS1 = 38
  Serial.print ("Arbitration Phase segment 2: ") ;
  Serial.println (settings.mArbitrationPhaseSegment2) ; // PS2 = 9
  Serial.print ("Arbitration Resynchronization Jump Width: ") ;
  Serial.println (settings.mArbitrationSJW) ; // SJW = 9
  Serial.print ("Arbitration Sample Point: ") ;
  Serial.println (settings.arbitrationSamplePointFromBitStart ()) ; // 81, meaning 81%
  Serial.print ("Data Phase segment 1: ") ;
  Serial.println (settings.mDataPhaseSegment1) ; // PS1 = 12
  Serial.print ("Data Phase segment 2: ") ;
  Serial.println (settings.mDataPhaseSegment2) ; // PS2 = 3
  Serial.print ("Data Resynchronization Jump Width: ") ;
  Serial.println (settings.mDataSJW) ; // SJW = 3
  Serial.print ("Data Sample Point: ") ;
  Serial.println (settings.dataSamplePointFromBitStart ()) ; // 81, meaning 81%
  Serial.print ("Consistency: ") ;
  Serial.println (settings.CANBitSettingConsistency ()) ; // 0, meaning Ok
  ...
}
```

The `samplePointFromBitStart` method returns sample point, expressed in per-cent of the bit duration from the beginning of the bit.

Note the computation may calculate a bit decomposition too far from the desired bit rate, but it is always consistent. You can check this by calling the `CANBitSettingConsistency` method.

You can change the property values for adapting to the particularities of your CAN network propagation time. By example, you can increment the `mArbitrationPhaseSegment1` value, and decrement the `mArbitrationPhaseSegment2` value in order to sample the `CAN Rx` pin later.

```
void setup () {
  ...
  ACAN2517FDSettings settings (ACAN2517FDSettings::OSC_4MHz10xPLL,
                               500 * 1000, ACAN2517FDSettings::DATA_BITRATE_x1) ;
```

```
  Serial.print ("mArbitrationBitRateClosedToDesiredRate: ") ;
  Serial.println (settings.mArbitrationBitRateClosedToDesiredRate) ; // 1 (--> is true)
  settings.mArbitrationPhaseSegment1 -= 8 ; // 63 -> 55: safe, 1 <= PS1 <= 256
  settings.mArbitrationPhaseSegment2 += 8 ; // 16 -> 24: safe, 1 <= PS2 <= 128
  settings.mArbitrationSJW += 8         ; // 16 -> 24: safe, 1 <= SJW <= PS2
  Serial.print ("Sample Point: ") ;
  Serial.println (settings.samplePointFromBitStart ()) ; // 68, meaning 68%
  Serial.print ("actual arbitration bit rate: ") ;
  Serial.println (settings.actualArbitrationBitRate ()) ; // 500000: ok, no change
  Serial.print ("Consistency: ") ;
  Serial.println (settings.CANBitSettingConsistency ()) ; // 0, meaning Ok
  ...
}
```

Be aware to always respect CAN bit timing consistency! The `MCP2517FD` constraints are:

$$1 \leqslant \texttt{mBitRatePrescaler} \leqslant 256$$

$$2 \leqslant \texttt{mArbitrationPhaseSegment1} \leqslant 256$$

$$1 \leqslant \texttt{mArbitrationPhaseSegment2} \leqslant 128$$

$$1 \leqslant \texttt{mArbitrationSJW} \leqslant \texttt{mArbitrationPhaseSegment2}$$

$$2 \leqslant \texttt{mDataPhaseSegment1} \leqslant 32$$

$$1 \leqslant \texttt{mDataPhaseSegment2} \leqslant 16$$

$$1 \leqslant \texttt{mDataSJW} \leqslant \texttt{mDataPhaseSegment2}$$

Miucrochips recommends using the same bit rate prescaler for arbitration and data bit rates.

Resulting actual bit rates are given by:

$$\text{Actual Arbitration Bit Rate} = \frac{\texttt{SYSCLK}}{\texttt{mBitRatePrescaler} \cdot (1 + \texttt{mArbitrationPhaseSegment1} + \texttt{mArbitrationPhaseSegment2})}$$

$$\text{Actual Data Bit Rate} = \frac{\texttt{SYSCLK}}{\texttt{mBitRatePrescaler} \cdot (1 + \texttt{mDataPhaseSegment1} + \texttt{mDataPhaseSegment2})}$$

And the sampling point (in per-cent unit) are given by:

$$\text{Arbitration Sampling Point} = 100 \cdot \frac{1 + \texttt{mArbitrationPhaseSegment1}}{1 + \texttt{mArbitrationPhaseSegment1} + \texttt{mArbitrationPhaseSegment2}}$$

$$\text{Data Sampling Point} = 100 \cdot \frac{1 + \texttt{mDataPhaseSegment1}}{1 + \texttt{mDataPhaseSegment1} + \texttt{mDataPhaseSegment2}}$$

19.2   The `CANBitSettingConsistency` method

This method checks the CAN bit decomposition (given by `mBitRatePrescaler`, `mArbitrationPhaseSegment1`, `mArbitrationPhaseSegment2`, `mArbitrationSJW`, `mDataPhaseSegment1`, `mDataPhaseSegment2`, `mDataSJW` property values) is consistent.

```
void setup () {
  ...
  ACAN2517FDSettings settings (ACAN2517FDSettings::OSC_4MHz10xPLL,
```

```
                                500 * 1000, ACAN2517FDSettings::DATA_BITRATE_x2) ;
  Serial.print ("mArbitrationBitRateClosedToDesiredRate: ") ;
  Serial.println (settings.mArbitrationBitRateClosedToDesiredRate) ; // 1 (--> is true)
  settings.mDataPhaseSegment1 = 0 ; // Error, mDataPhaseSegment1 should be >= 1 (and <= 32)
  Serial.print ("Consistency: 0x") ;
  Serial.println (settings.CANBitSettingConsistency (), HEX) ; // != 0, meaning error
  ...
}
```

The `CANBitSettingConsistency` method returns 0 if CAN bit decomposition is consistent. Otherwise, the returned value is a bit field that can report several errors – see table 8.

The `ACAN2517FDSettings` class defines static constant properties that can be used as mask error. For example:

```
public: static const uint32_t kBitRatePrescalerIsZero = 1 << 0 ;
```

Bit	Error Name	Error
0	kBitRatePrescalerIsZero	mBitRatePrescaler $== 0$
1	kBitRatePrescalerIsGreaterThan256	mBitRatePrescaler > 256
2	kArbitrationPhaseSegment1IsLowerThan2	mArbitrationPhaseSegment1 < 2
3	kArbitrationPhaseSegment1IsGreaterThan256	mArbitrationPhaseSegment1 > 256
4	kArbitrationPhaseSegment2IsZero	mArbitrationPhaseSegment2 $== 0$
5	kArbitrationPhaseSegment2IsGreaterThan128	mArbitrationPhaseSegment2 > 128
6	kArbitrationSJWIsZero	mArbitrationSJW $== 0$
7	kArbitrationSJWIsGreaterThan128	mArbitrationSJW > 128
8	kArbitrationSJWIsGreaterThanPhaseSegment1	mArbitrationSJW $>$ mArbitrationPhaseSegment1
9	kArbitrationSJWIsGreaterThanPhaseSegment2	mArbitrationSJW $>$ mArbitrationPhaseSegment2
10	kArbitrationTQCountNotDivisibleByDataBitRateFactor	See section 19.3 page 37
11	kDataPhaseSegment1IsLowerThan2	mDataPhaseSegment1 < 2
12	kDataPhaseSegment1IsGreaterThan32	mDataPhaseSegment1 > 32
13	kDataPhaseSegment2IsZero	mDataPhaseSegment2 $== 0$
14	kDataPhaseSegment2IsGreaterThan16	mDataPhaseSegment2 > 16
15	kDataSJWIsZero	mDataSJW $== 0$
16	kDataSJWIsGreaterThan16	mDataSJW > 16
17	kDataSJWIsGreaterThanPhaseSegment1	mDataSJW $>$ mDataPhaseSegment1
18	kDataSJWIsGreaterThanPhaseSegment2	mDataSJW $>$ mDataPhaseSegment2

Table 8 – The `ACAN2517FDSettings::CANBitSettingConsistency` method error codes

19.3   The `kArbitrationTQCountNotDivisibleByDataBitRateFactor` error

This error occurs when you have changed the properties relative to arbitration and / or data bit rates, and the resulting values provide a data bit rate that is not an integer multiple of arbitration bit rate, that is the `ACAN2517FDSettings::dataBitRateIsAMultipleOfArbitrationBitRate` method returns `false`.

19.4   The `actualArbitrationBitRate` method

The `actualArbitrationBitRate` method returns the actual bit computed from `mBitRatePrescaler`, `mPropagationSegment`, `mArbitrationPhaseSegment1`, `mArbitrationPhaseSegment2`, `mArbitrationSJW` property values.

```
void setup () {
  ...
  ACAN2517FDSettings settings (ACAN2517FDSettings::OSC_4MHz10xPLL,
                               440 * 1000, ACAN2517FDSettings::DATA_BITRATE_x1) ;
  Serial.print ("mArbitrationBitRateClosedToDesiredRate: ") ;
```

```
   Serial.println (settings.mArbitrationBitRateClosedToDesiredRate) ; // 0 (--> is false)
   Serial.print ("actual arbitration bit rate: ") ;
   Serial.println (settings.actualArbitrationBitRate ()) ; //  444,444 bit/s
   ...
}
```

Note.   If CAN bit settings are not consistent (see section 19.2 page 36), the returned value is irrelevant.

19.5   The `exactArbitrationBitRate` method

```
bool ACAN2517FDSettings::exactArbitrationBitRate (void) const ;
```

The `exactArbitrationBitRate` method returns `true` if the actual arbitration bit rate is equal to the desired arbitration bit rate, and `false` otherwise.

Note.   If CAN bit settings are not consistent (see section 19.2 page 36), the returned value is irrelevant.

19.6   The `exactDataBitRate` method

```
bool ACAN2517FDSettings::exactDataBitRate (void) const ;
```

The `exactDataBitRate` method returns `true` if the actual data bit rate is equal to the desired data bit rate, and `false` otherwise.

Note.   If CAN bit settings are not consistent (see section 19.2 page 36), the returned value is irrelevant.

19.7   The `ppmFromDesiredArbitrationBitRate` method

```
uint32_t ACAN2517FDSettings::ppmFromDesiredArbitrationBitRate (void) const ;
```

The `ppmFromDesiredArbitrationBitRate` method returns the distance from the actual arbitration bit rate to the desired arbitration bit rate, expressed in part-per-million (ppm): $1 \text{ ppm} = 10^{-6}$. In other words, $10,000 \text{ ppm} = 1\%$.

Note.   If CAN bit settings are not consistent (see section 19.2 page 36), the returned value is irrelevant.

19.8   The `ppmFromDesiredDataBitRate` method

```
uint32_t ACAN2517FDSettings::ppmFromDesiredDataBitRate (void) const ;
```

The `ppmFromDesiredDataBitRate` method returns the distance from the actual data bit rate to the desired data bit rate, expressed in part-per-million (ppm): $1 \text{ ppm} = 10^{-6}$. In other words, $10,000 \text{ ppm} = 1\%$.

Note.   If CAN bit settings are not consistent (see section 19.2 page 36), the returned value is irrelevant.

19.9   The `arbitrationSamplePointFromBitStart` method

```
uint32_t ACAN2517FDSettings::arbitrationSamplePointFromBitStart (void) const ;
```

The `arbitrationSamplePointFromBitStart` method returns the distance of sample point from the start of the arbitration CAN bit, expressed in part-per-cent (ppc): $1 \text{ ppc} = 1\% = 10^{-2}$. It is a good practice to get sample point from 65% to 80%. The bit rate calculator tries to set the sample point at 80%.

Note.   If CAN bit settings are not consistent (see section 19.2 page 36), the returned value is irrelevant.

19.10   The `dataSamplePointFromBitStart` method

```
uint32_t ACAN2517FDSettings::dataSamplePointFromBitStart (void) const ;
```

The `dataSamplePointFromBitStart` method returns the distance of sample point from the start of the data CAN bit, expressed in part-per-cent (ppc): $1 \text{ ppc} = 1\% = 10^{-2}$. It is a good practice to get sample point from 65% to 80%. The bit rate calculator tries to set the sample point at 80%.

Note.   If CAN bit settings are not consistent (see), the returned value is irrelevant.

19.11   Properties of the `ACAN2517FDSettings` class

All properties of the `ACAN2517FDSettings` class are declared `public` and are initialized (table 9). The default values of properties from `mDesiredBitRate` until `mTripleSampling` corresponds to a CAN bit rate of `QUARTZ_FREQUENCY` / 64, that is 250,000 bit/s for a 16 MHz quartz.

Property	Type	Initial value	Comment
mOscillator	Oscillator	Constructor argument	
mSysClock	uint32_t	Constructor argument	
mDesiredBitRate	uint32_t	Constructor argument	
mBitRatePrescaler	uint16_t	0	See section 19.1 page 31
mArbitrationPhaseSegment1	uint16_t	0	See section 19.1 page 31
mArbitrationPhaseSegment2	uint8_t	0	See section 19.1 page 31
mArbitrationSJW	uint8_t	0	See section 19.1 page 31
mArbitrationBitRateClosedTo-DesiredRate	bool	false	See section 19.1 page 31
mDataPhaseSegment1	uint16_t	0	See section 19.1 page 31
mDataPhaseSegment2	uint8_t	0	See section 19.1 page 31
mDataSJW	uint8_t	0	See section 19.1 page 31
mDataBitRateClosedToDesiredRate	bool	false	See section 19.1 page 31
mTXCANIsOpenDrain	bool	false	See section 19.11.1 page 39
mINTIsOpenDrain	bool	false	See section 19.11.2 page 40
mCLKOPin	CLKOpin	CLKO_DIVIDED_BY_10	See section 19.11.3 page 40
mISOCRCEnabled	bool	true	See section 19.11.5 page 41
mRequestedMode	RequestedMode	NormalFD	See section 19.11.4 page 40
mDriverTransmitFIFOSize	uint16_t	16	See section 9 page 17
mControllerTransmitFIFOSize	uint8_t	32	See section 9 page 17
mControllerTransmitFIFOPayload	PayloadSize	PAYLOAD_64	See section 9 page 17
mControllerTransmitFIFOPriority	uint8_t	0	See section 9 page 17
mControllerTransmitFIFO-RetransmissionAttempts	RetransmissionAttempts	UnlimitedNumber	See section 9 page 17
mControllerTXQSize	uint8_t	0	See section 10 page 18
mControllerTXQBufferPayload	PayloadSize	PAYLOAD_64	See section 10 page 18
mControllerTXQBufferPriority	uint8_t	31	See section 10 page 18
mControllerTXQBuffer-RetransmissionAttempts	RetransmissionAttempts	UnlimitedNumber	See section 10 page 18
mDriverReceiveFIFOSize	uint16_t	32	See section 11 page 19
mControllerReceiveFIFOPayload	PayloadSize	PAYLOAD_64	See section 11 page 19
mControllerReceiveFIFOSize	uint8_t	32	See section 11 page 19

Table 9 – Properties of the `ACAN2517FDSettings` class

19.11.1   The `mTXCANIsOpenDrain` property

This property defines the outpiut mode of the `MCP2517FD` `TXCAN` pin:

- if `false` (default value), the `TXCAN` pin is a push/pull output;

- if `true`, the `TXCAN` pin is an open drain output.

19.11.2 The `mINTIsOpenDrain` property

This property defines the outpiut mode of the `MCP2517FD INT` pin:

- if `false` (default value), the `INT` pin is a push/pull output;

- if `true`, the `INT` pin is an open drain output.

19.11.3 The `CLKO/SOF` pin

The `CLKO/SOF` pin of the `MCP2517FD` controller is an output pin has five functions[13]:

- output *internally generated clock*;

- output *internally generated clock* divided by 2;

- output *internally generated clock* divided by 4;

- output *internally generated clock* divided by 10;

- output `SOF` ("Start Of Frame").

By default, after power on, `CLKO/SOF` pin outputs *internally generated clock* divided by 10.

The `ACAN2517FDSettings` class defines an enumerated type for specifying these settings:

```
class ACAN2517FDSettings {
  public: typedef enum {CLKO_DIVIDED_BY_1, CLKO_DIVIDED_BY_2,
                        CLKO_DIVIDED_BY_4, CLKO_DIVIDED_BY_10,
                        SOF} CLKOpin ;
  ...
} ;
```

The `mCLKOPin` property lets you select the `CLKO/SOF` pin function; by default, this property value is `CLKO_DIVIDED_BY_10`, that corresponds to `MCP2517FD` power on setting. For example:

```
    ACAN2517FDSettings settings (ACAN2517FDSettings::OSC_4MHz10xPLL, CAN_BIT_RATE) ;
    ...
    settings.mCLKOPin = ACAN2517FDSettings::SOF ;
    ...
    const uint32_t errorCode = can.begin (settings, [] { can.isr () ; }) ;
```

19.11.4 The `mRequestedMode` property

This property defines the mode requested at this end of the configuration: `NormalFD` (default value), `InternalLoopBack`, `ExternalLoopBack`, `ListenOnly`.

---

[13]*Internally generated clock* is not `SYSCLK`, see figure 8 page 16.

19.11.5   The `mISOCRCEnabled` property

This property enables ISO CRC in CAN FD Frames bit:

- **`true`** (default): include Stuff Bit Count in CRC Field and use Non-Zero CRC Initialization Vector according to ISO 11898-1:2015:

- **`false`**: do NOT include Stuff Bit Count in CRC Field and use CRC Initialization Vector with all zeros.

This setting correspondonds to the `ISOCRCEN` bit of the `CiCON` register.
